

ET recovery dynamics in Mediterranean drylands —
universal timescale ($\tau \approx 3$ d), management-scaled amplitude ($\sim 4\times$)

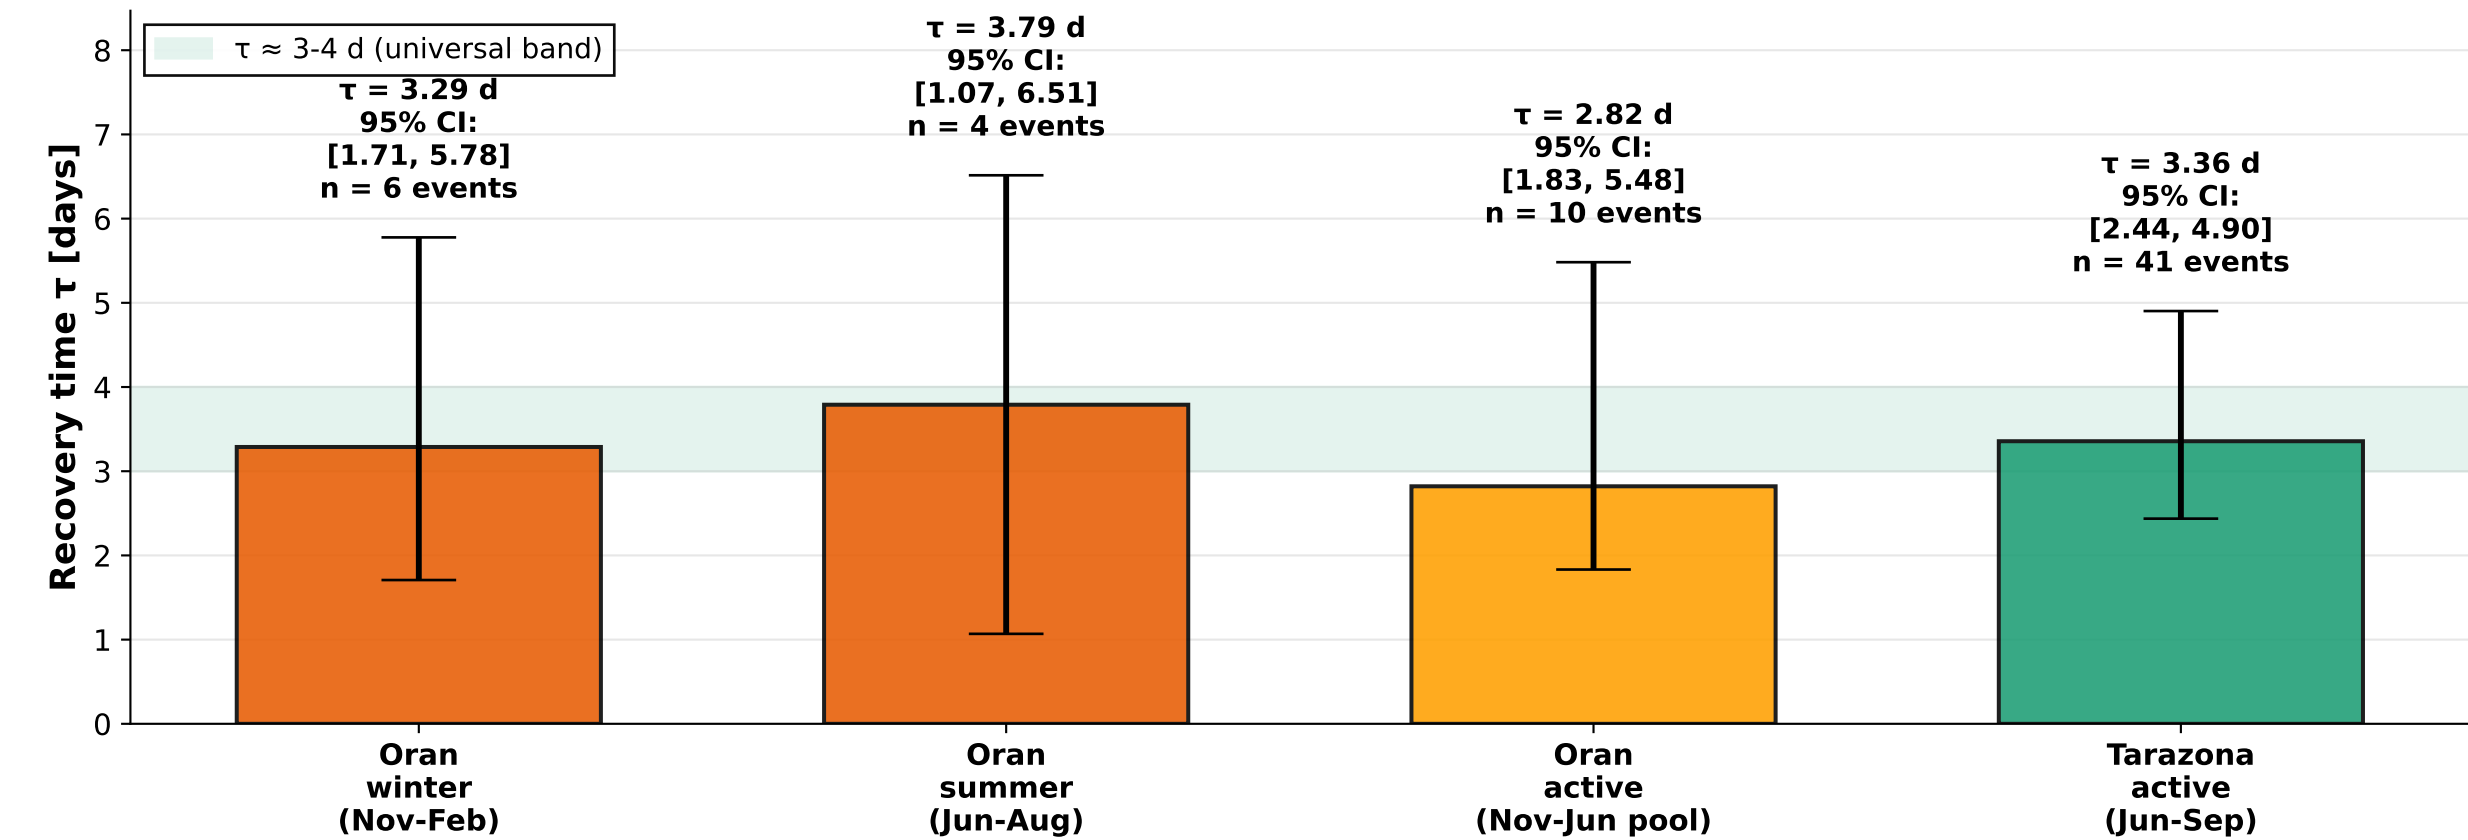

(a) Tarazona — drip-irrigated almond (n events = 41)

(b) Oran — rainfed cereal (n events = 10)

(c) τ across 4 strata — same value despite different sites & seasons

What this panel shows:

Same τ is observed under:

- Different SITES (Oran vs Tarazona)
- Different SEASONS (winter vs summer)
- Different POOLINGS

All pairwise $|\Delta\tau| < \text{MDE}$ ($\alpha=0.05$)

→ $\tau \approx 3$ d is invariant
= effective ecosystem-atmosphere
relaxation timescale, not
a site- or management-specific
artifact.
